Exercises for Database Implementation TUM

Viktor Leis (leis@in.tum.de)

Assignment 7 (Optional)

Excercise 1 (LLVM Code Generation, 10 Bonus Points)

Based on the simple LLVM example program (fibonacci.cpp, see our class website), create an LLVM-based "subscript"-compiler for simple binary arithmetic expressions. Example: $(v_0 + v_1) \times (v_2 - v_3)$, in tree representation:

Write a function similar to CreateFibFunction that takes an llvm::Module (like fibonacci.cpp), an llvm::LLVMContext (like fibonacci.cpp) and the root of a binary arithmetic expression tree as parameters. The tree's nodes contain the operators $\times, \div, +, -$, constants and variables (v_0, \ldots, v_{n-1}) .

The function generates a function f that can be called with n integer argments and returns the result of the expression, e.g. in the example above f(1,2,5,2) returns 9 (since $(1+2) \times (5-2) = 9$).

Your code may be completely independent from your database system's code base.
